# SELECTIVE INERTIAL BLOCK-ITERATIVE SCHEMES FOR A CLASS OF VARIATIONAL INEQUALITIES AND APPLICATIONS 

Nguyen Thi Quynh Anh<br>The People's Police University of Technology and Logistics.<br>Thuan Thanh, Bac Ninh, Viet Nam.<br>e-mail: quynhanhnguyen0178@gmail.com

#### Abstract

Our purpose in this paper is to present inertial block-iterative schemes with selective technique for finding a solution of a variational inequality problem over the set of common fixed points of a finite family of demiclosed quasinonexpansive mappings in Hilbert spaces. First, we introduce a basic scheme and show that any sequence, generated by this scheme, converges weakly to a point in the common fixed point set. Then, based on a specific combination of the scheme with the steepest-descent method, we propose new schemes, strong convergence of which is proved without the approximately shrinking and boundedly regular assumptions on the mappings and their fixed point sets, respectively, that are usually required recently in literature. An application to study a networked system and computational experiments are given for illustration and comparison.

## 1. Introduction

Let $H$ be a Hilbert space equipped with the inner product $\langle.,$.$\rangle , the cor-$ responding norm $\|\cdot\|$ and with the identity mapping $I$. Let $T_{i}$, for $i \in L:=$ $\{1, \ldots, m\}$ with a finite integer $m \geq 1$, be a demiclosed quasi-nonexpansive mapping on $H$ with the property $\cap_{i \in L} \operatorname{Fix}\left(T_{i}\right) \neq \emptyset$ where $\operatorname{Fix}\left(T_{i}\right)=\{p \in H$ : $\left.p=T_{i} p\right\}$, the fixed point set of $T_{i}$. The considered problem in this paper is to find a point

$$
\begin{equation*}
p_{*} \in C:=\cap_{i \in L} \operatorname{Fix}\left(T_{i}\right) \text { such that }\left\langle F p_{*}, p_{*}-p\right\rangle \leq 0 \forall p \in C \tag{1.1}
\end{equation*}
$$

Key words: Quasi-nonexpansive mapping • fixed point • variational inequality • blockiterative scheme..
2010 AMS Classification: 46N10, 47H10, 47J25,47N10, 65F10,65J99.
where $F$ is $\eta$-strongly monotone and $l$-Lipschitz continuous on $H$.
When $T_{i}$ is a nonexpansive mapping, Yamada [31] proposed the hybrid steepest-descent method,

$$
\begin{equation*}
x^{k+1}=\left(I-t_{k} \mu F\right) T x^{k}, k \geq 0 \tag{1.2}
\end{equation*}
$$

where $\mu \in\left(0,2 \eta / l^{2}\right)$ is a fixed number and $T$ is either $T_{m} T_{m-1} \ldots T_{1}$ or $\sum_{i \in L} \omega_{i} T_{i}$ with $\omega_{i} \in(0,1)$ and $\sum_{i \in L} \omega_{i}=1$, and proved the strong convergence of method (1.2) under two conditions on $t_{k}$, one of which is that
$(t) t_{k} \in(0,1)$ for all $k \geq 1, \lim _{k \rightarrow \infty} t_{k}=0$ and $\sum_{k \geq 0} t_{k}=\infty$.
In [7], Ng. Buong and L.T.T. Duong gave a modification of (1.2),

$$
\begin{equation*}
x^{k+1}=\left(1-\alpha_{k}\right) x^{k}+\alpha_{k}\left(I-t_{k} \mu F\right) T^{k} x^{k}, k \geq 0 \tag{1.3}
\end{equation*}
$$

$\alpha_{k} \in[\varepsilon, 1]$ and $T^{k}=T_{m}^{k} T_{m-1}^{k} \ldots T_{1}^{k}$ where $T_{i}^{k}=I+\beta_{i}^{k}\left(T_{i}-I\right), \beta_{k}$ has the property
$(\beta) \beta_{i}^{k} \in[\underline{\beta}, \bar{\beta}] \subset(0,1)$
and $t_{k}$ satisfies only condition $(t)$.
When each $T_{i}$ is quasi-nonexpansive, method (1.2) and its modifications have been recently investigated in [9-15]. Cegielski and Zalas [12] proposed the generalized hybrid steepest-descent method with selective technique, called selective hybrid steepest descent method,

$$
\begin{equation*}
x^{k+1}=\left(I-t_{k} F\right) T_{i_{k}} x^{k} \tag{1.4}
\end{equation*}
$$

where $i_{k}$ is selected by

$$
\begin{equation*}
i_{k}=\arg \max _{i \in L}\left\|T_{i} x^{k}-x^{k}\right\| \tag{1.5}
\end{equation*}
$$

The strong convergence of (1.4)-(1.5) is guaranteed when the mapping $T_{i}$ is approximately shrinking for each $i \in L$ and the family $\mathcal{F}:=\left\{\operatorname{Fix}\left(T_{i}\right): i \in L\right\}$ is boundedly regular. A combination of method (1.4)-(1.5) with the outer approximations, has been presented by Gibali et al. [15] with the same properties of $T_{i}$ and $\mathcal{F}$ as the above. The last two conditions are deleted by He and Tian [17], when $T_{i}$ is nonexpansive and then $T_{i_{k}}$ in the equivalent form to (1.4), $x^{k+1}=T_{i_{k}}\left(I-t_{k} F\right) x^{k}$, is replaced by $I+\beta_{i}^{k}\left(T_{i_{k}}-I\right)$. Very recently, Ng . Buong [8] gave a scheme, that is a specific combination of the block-iterative method, introduced by Aleyner and Reich [1] for the convex feasibility problem, with the steepest-descent method and proved the strong convergence without the approximately shrinking and boundedly regular assumptions, where $\mu$ is still chosen in dependence of $\eta$ and $l$.

To speed up the convergence of the Krasnoselskii [20]- Mann [25] iterative method of finding a point in $C$, for the general case $m=\infty$, Maingé [22,23] suggested a combination of this method with an inertial effect, that is

$$
\begin{align*}
u^{k} & =x^{k}+\theta_{k}\left(x^{k}-x^{k-1}\right) \\
x^{k+1} & =\left(1-\alpha_{k}\right) x^{k}+\alpha_{k} T^{k} u^{k} \tag{1.6}
\end{align*}
$$

where $T^{k}=\left(1 / \gamma^{k}\right) \sum_{i \geq 1} \gamma_{i} T_{i}$ with $\gamma_{i}>0, \sum_{i \geq 1} \gamma_{i}=1$ and $\gamma^{k}=\sum_{i=1}^{k} \gamma_{i}$, $\alpha_{k} \in(0,2)$ and $\theta_{k}$ is chosen such that
(c1) $\left\{\theta_{k}\right\} \subset[0, \theta]$, where $\theta \in[0,1)$.
(c2) $\sum_{k \geq 1} \theta_{k}\left\|x^{k}-x^{k-1}\right\|^{2}<\infty$.
When $m=1$ and $T$ is nonexpasnive on $H$, Bot et al. [6] also studied the convergence of (1.6) with removing condition (c2). But, they required a strict condition on $\theta_{k}$ and $\alpha_{k}$. Shehu [27] combined the inertial effect $u_{k}$ in (1.6) with the Ishikawa [19] iterative method under weaker conditions on the inertial factor $\theta_{k}$ and iterative parameters $\alpha_{k}$ than those in [6]. Recently, in order to obtain a strongly convergent sequence, Tan et al. [29], by combining the inertial Krasnoselskii-Mann iterative method with the Halpern [16] and Moudafi [26] viscosity approximation methods under a new condition on $\theta_{k}$,
(c3) $\lim _{k \rightarrow \infty} \frac{\theta_{k}}{t_{k}}\left\|x^{k}-x^{k-1}\right\|=0$.
In this paper, based on method (1.3) and a reconstruction of a method in [1] with the inertial effect $u_{k}$, we first propose an inertial block-iterative scheme with selective technique, that converges weakly to a point in $C$. Next, for solving (1.1), we introduce new block-iterative schemes and prove their strong convergence without the approximately shrinking and boundedly regular assumptions on $T_{i}$ and $\mathcal{F}$, respectively. Moreover, the parameter $\mu$ in our schemes is chosen through an adaptive way.

We organize the rest of this paper as follows. In Section 2, we list some terminologies, using in this paper, and related facts, that will be used in the proof of our results. In Section 3, we suggest two block-iterative schemes with several modifications and give convergence theorems for the schemes and modifications. An application to a networked system and computational experiments are given for illustration and comparison.

## 2. Preliminaries

We remember that an operator $T$ in $H$ is called (see, [14]):

- nonexpansive or contractive if $\|T x-T y\| \leq a\|x-y\|$ with $a=1$ or $a \in[0,1)$, respectively, for all $x, y \in H$.
- quasi-nonexpansive, if $\operatorname{Fix}(T) \neq \emptyset$ and $\|T x-p\| \leq\|x-p\|$ for all $x \in H$ and $p \in \operatorname{Fix}(T)$.
- a cutter, if $\operatorname{Fix}(T) \neq \emptyset$ and $\langle p-T x, x-T x\rangle \leq 0$ for all $x \in H$ and $p \in \operatorname{Fix}(T)$.
- $\rho$-strongly quasi-nonexpansive, if $\operatorname{Fix}(T) \neq \emptyset$ and, for all $x \in H$ and $p \in \operatorname{Fix}(T),\|T x-p\|^{2} \leq\|x-p\|^{2}-\rho\|T x-x\|^{2}$ where the real number $\rho \geq 0$.
- approximately shrinking on a subset $D \subseteq H$, if for any sequence $\left\{x^{k}\right\} \subseteq D$ the following implication holds

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|T x^{k}-x^{k}\right\|=0 \Longrightarrow \lim _{k \rightarrow \infty} \rho\left(x^{k}, \operatorname{Fix}(T)\right)=0 \tag{2.1}
\end{equation*}
$$

- demiclosed if for any sequence $\left\{x^{k}\right\} \subset H$ it holds
( $x^{k}$ converges weakly to $x$ and $\left.\left\|T x^{k}-x^{k}\right\| \rightarrow 0\right) \Longrightarrow x \in \operatorname{Fix}(T)$.
- The family $\left\{\operatorname{Fix}\left(T_{i}\right): i \in L\right\}$ is called boundedly regular, if for any bounded subset $D \subset H$ and for any $\varepsilon>0$, there exists a real number $\delta>0$ such that for any $x \in D$

$$
\max _{i \in L} \rho\left(x, C_{i}\right) \leq \delta \Longrightarrow \rho(x, C) \leq \varepsilon,
$$

where $\rho(x, C)=\inf _{y \in C}\|x-y\|$.
Clearly, a $\rho$-strongly quasi-nonexpansive mapping $T$ with $\rho=0$ is quasinonexpansive and a nonexpansive mapping $T$ with $\operatorname{Fix}(T) \neq \emptyset$ is quasi nonexpansive. In this case $\operatorname{Fix}(T)$ is closed and convex. A $\rho$-strongly quasinonexpansive mapping $T$ with $\rho=1$ is a cutter. A mapping $T$ is $\rho$-strongly quasi-nonexpansive, if and only if $\lambda\langle p-x, T x-x\rangle \geq\|T x-x\|^{2}$ for all $x \in H$ and all $p \in \operatorname{Fix}(T)$, where $\lambda=2 /(\rho+1)$. It is worth mentioning that in a general Hilbert space $H(2.2)$ is only a necessary condition for implication (2.1) and even a firmly nonexpansive mapping may not have this property (see, [15]). A mapping $F: H \rightarrow H$ is said to be $\eta$-strongly monotone and $\gamma$-Lipschitz continuous, if it satisfies, respectively, the conditions $\langle F x-F y, x-y\rangle \geq \eta\|x-y\|^{2}$ and $\|F x-F y\| \leq \gamma\|x-y\|$ for all $x, y \in H$ with $\gamma \geq \eta>0$. It is well known that

$$
\|x+y\|^{2} \leq\|x\|^{2}+2\langle y, x+y\rangle \forall x, y \in H .
$$

Lemma 2.1 ([31]) Let $H$ be a real Hilbert space and let $F$ be an $\eta$-strongly monotone and l-Lipschitz continuous mapping on $H$ with some positive constants $l \geq \eta>0$. Let $T^{\mu}=I-\mu F$ and let $T^{t, \mu}=I-t \mu F$. Then, for a fixed number $\mu \in\left(0,2 \eta / l^{2}\right)$ and any $t \in(0,1), I-\mu F$ and $I-t \mu F$ are all contractions with coefficients $1-\tau$ and $1-t \tau$, respectively, where $\tau=(1 / 2) \mu\left(2 \eta-\mu l^{2}\right)$.
Lemma 2.2 ([30]) Let $\left\{a_{k}\right\},\left\{b_{k}\right\}$ and $\left\{c_{k}\right\}$ be sequences of real numbers such that, for all $k \geq 0, a_{k+1} \leq\left(1-b_{k}\right) a_{k}+b_{k} c_{k} ; a_{k} \geq 0$; $b_{k}$ satisfies a condition of type $(t)$; and either $\sum_{k=1}^{\infty} b_{k}\left|c_{k}\right|<\infty$ or $\limsup _{k \rightarrow \infty} c_{k} \leq 0$. Then, $\lim _{k \rightarrow \infty} a_{k}=0$.
Lemma 2.3 ([22]) Let $\left\{a_{k}\right\}$ be a sequence of real numbers with a subsequence $\left\{l_{k}\right\}$ of $\{k\}$ such that $a_{l_{k}}<a_{l_{k}+1}$. Then, there exists a nondecreasing sequence $\left\{m_{k}\right\} \subseteq\{k\}$ such that $m_{k} \rightarrow \infty, a_{m_{k}} \leq a_{m_{k}+1}$ and $a_{k} \leq a_{m_{k}+1}$ for all (sufficiently large) numbers $k \geq 0$. In fact, $m_{k}=\max \left\{l \leq k: a_{l} \leq a_{l+1}\right\}$.

Lemma $2.4([2,3])$ Let $\left\{\varphi_{k}\right\} \subset[0, \infty)$ and $\left\{\delta_{k}\right\} \subset[0, \infty)$ verify
(i) $\varphi_{k+1}-\varphi_{k} \leq \theta_{k}\left(\varphi_{k}-\varphi_{k-1}\right)+\delta_{k}$,
(ii) $\sum_{k=1}^{\infty} \delta_{k}<\infty$,
and there holds condition (c1). Then, $\lim _{k \rightarrow \infty} \varphi_{k}$ exists and $\sum_{k=1}^{\infty}\left[\varphi_{k+1}-\right.$ $\left.\varphi_{k}\right]_{+}<\infty$, where $[t]_{+}=\max \{t, 0\}$ for any $t \in \mathbb{R}$.

## 3. Main results

In order to find a point in $C$, we consider the following inertial blockiterative scheme with selective technique, a main scheme.
Main scheme:
St. 0 Choose any two points $x^{-1}, x^{0} \in H$ such that $x^{-1} \neq x^{0}$ and an integer $s \geq 1$. Set $k:=0$.

St. 1 Calculate $u^{k}=x^{k}+\theta_{k}\left(x^{k}-x^{k-1}\right)$, where $\theta_{k}$ satisfies (c1) and (c2).
St. 2 For $t=1, \cdots, s$, let $L_{t}^{k}$ be an ordered subset of $L$ such that $L=L_{1}^{k} \cup$ $\cdots \cup L_{s}^{k}$ and define $y^{k, t}$ by the rule:

$$
\begin{equation*}
y^{k, 0}:=u^{k}, y^{k, t}=T_{i_{\max }(t)} y^{k, t-1}, i_{\max }(t)=\arg \max _{i(t) \in L_{t}^{k}} p_{i(t)}\left(y^{k, t-1}\right) \tag{3.1}
\end{equation*}
$$

where $p_{i}(x)=\left\|T_{i} x-x\right\|$ for any $x \in H$.
St. 3 Compute $x^{k+1}=\left(1-\alpha_{k}\right) x^{k}+\alpha_{k} y^{k, s}$ with $\alpha_{k} \in[\varepsilon, 1]$. Then, set $x^{k-1}:=$ $x^{k}, x^{k}:=x^{k+1}$ and $k:=k+1$. Return to St.1.

## Remark

1. Clearly, $u^{k}$ is a point in $C$ if and only if $p_{i_{\max }(t)}\left(y^{k, t-1}\right)=0$ for $t=1, \ldots, s$. We will show that any sequence, generated by the main scheme, converges weakly to a point in $C$. For solving the stated problem, we replace $\left\{x^{k+1}\right\}$ in St. 3 by a new $x^{k+1}$, defined by

$$
\begin{equation*}
x^{k+1}=\left(1-\alpha_{k}\right)\left(I-t_{k} \mu_{k} F\right) x^{k}+\alpha_{k} y^{k, s} \tag{3.2}
\end{equation*}
$$

where $t_{k}$ satisfies $(t)$,

$$
\mu_{k}=\left\{\begin{array}{lc}
\frac{\left\langle F x^{k}-F x^{k-1}, x^{k}-x^{k-1}\right\rangle}{\left\|F x^{k}-F x^{k-1}\right\|^{2}}, & x^{k} \neq x^{k-1} \\
\mu_{k-1}, & \text { otherwise }
\end{array}\right.
$$

and condition (c2) is replaced by (c3).
We have the following results.
Theorem 3.1 Any sequence $\left\{x^{k}\right\}$, generated by the main scheme, converges weakly to a point in $C$, as $k \rightarrow \infty$.

Proof. Let $p$ be any fixed point in $C$. Using the definition of $y^{k, t}$ and the properties of $T_{i_{\max }(t)}$, we get

$$
\begin{aligned}
\left\|y^{k, t}-p\right\|^{2} & =\left\|T_{i_{\max }(t)} y^{k, t-1}-p\right\|^{2} \\
& \leq\left\|y^{k, t-1}-p\right\|^{2}-\rho_{\min }\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}
\end{aligned}
$$

for all $t=1,2, \ldots, s$. Summing the last inequalities with $t=1, \ldots, s$ and noting $y^{k, 0}=u^{k}$, we obtain

$$
\begin{equation*}
\left\|y^{k, s}-p\right\|^{2} \leq\left\|u^{k}-p\right\|^{2}-\rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \tag{3.3}
\end{equation*}
$$

On the other hand,

$$
\begin{align*}
\left\|u^{k}-p\right\|^{2} & =\left\|x^{k}-p+\theta_{k}\left(x^{k}-x^{k-1}\right)\right\|^{2} \\
& =\left\|x^{k}-p\right\|^{2}+2 \theta_{k}\left\langle x^{k}-p, x^{k}-x^{k-1}\right\rangle+\theta_{k}^{2}\left\|x^{k}-x^{k-1}\right\|^{2} \tag{3.4}
\end{align*}
$$

From the well known property,

$$
\langle u, v\rangle=-\frac{1}{2}\|u-v\|^{2}+\frac{1}{2}\|u\|^{2}+\frac{1}{2}\|v\|^{2}
$$

for any two points $u, v \in H$, it follows that

$$
\left\langle x^{k}-p, x^{k}-x^{k-1}\right\rangle=-\frac{1}{2}\left\|x^{k-1}-p\right\|^{2}+\frac{1}{2}\left\|x^{k}-p\right\|^{2}+\frac{1}{2}\left\|x^{k}-x^{k-1}\right\|^{2}
$$

This together with (3.3), the definition of $x^{k+1}$ in St. 3 and (3.4) implies that

$$
\begin{gather*}
\left\|x^{k+1}-p\right\|^{2}-\left\|x^{k}-p\right\|^{2} \leq \theta_{k}\left(\left\|x^{k}-p\right\|^{2}-\left\|x^{k-1}-p\right\|^{2}\right)+2 \theta_{k}\left\|x^{k}-x^{k-1}\right\|^{2} \\
-\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \tag{3.5}
\end{gather*}
$$

since $\theta_{k}^{2} \leq \theta_{k}$. Therefore,

$$
\left\|x^{k+1}-p\right\|^{2}-\left\|x^{k}-p\right\|^{2} \leq \theta_{k}\left(\left\|x^{k}-p\right\|^{2}-\left\|x^{k-1}-p\right\|^{2}\right)+2 \theta_{k}\left\|x^{k}-x^{k-1}\right\|^{2}
$$

Using Lemma 2.4 with $\varphi_{k}=\left\|x^{k}-p\right\|^{2}$ and $\delta_{k}=\theta_{k}\left\|x^{k}-x^{k-1}\right\|^{2}$, we have the existence of $\lim _{k \rightarrow \infty}\left\|x^{k}-p\right\|$. Consequently, $\left\{x^{k}\right\}$ is bounded. Moreover, from (3.5) we can deduce that

$$
\begin{aligned}
\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \leq & \left\|x^{k}-p\right\|^{2}-\left\|x^{k+1}-p\right\|^{2}+2 \theta_{k}\left\|x^{k}-x^{k-1}\right\|^{2} \\
& +\theta_{k}\left(\left\|x^{k}-p\right\|^{2}-\left\|x^{k-1}-p\right\|^{2}\right)
\end{aligned}
$$

Again, by using Lemma 2.4, we get $\sum_{k=1}^{\infty}\left[\left\|x^{k}-p\right\|^{2}-\left\|x^{k-1}-p\right\|^{2}\right]_{+}<\infty$. Hence,

$$
\varepsilon \rho_{\min } \sum_{k=1}^{\infty} \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}<\infty
$$

It means that

$$
\lim _{k \rightarrow \infty} \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}=0
$$

which is equivalent to

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}=0 \tag{3.6}
\end{equation*}
$$

for $t=1, \ldots, s$. Therefore, from (3.1) and (3.6) we have

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|y^{k, t}-y^{k, t-1}\right\|=0 \tag{3.7}
\end{equation*}
$$

Hence, $\lim _{k \rightarrow \infty}\left\|y^{k, t}-u^{k}\right\|=0$, for $t=1, \ldots, s$, as $y^{k, 0}=u^{k}$. Further, from the definition of $u^{k}$ with properties (c1) and (c2), we obtain

$$
\left\|u^{k}-x^{k}\right\|^{2}=\theta_{k}^{2}\left\|x^{k}-x^{k-1}\right\|^{2} \leq \theta_{k}\left\|x^{k}-x^{k-1}\right\|^{2} \Longrightarrow 0
$$

as $k \rightarrow \infty$. Thus,

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|y^{k, t}-x^{k}\right\|=0 \tag{3.8}
\end{equation*}
$$

for $t=1, \ldots, s$. Since $\left\{x^{k}\right\}$ is bounded, there exists a subsequence $\left\{x^{n_{k}}\right\} \subset\left\{x^{k}\right\}$ such that $\left\{x^{n_{k}}\right\}$ converges weakly to a point $\tilde{p} \in H$. Noting (3.7) and (3.8),

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|y^{n_{k}, t-1}-x^{n_{k}}\right\|=0 \tag{3.9}
\end{equation*}
$$

for $t=1, \ldots, s$. As $L=L_{1}^{n_{k}} \cup \cdots \cup L_{s}^{n_{k}}$, for each $i \in L$ there exists at least an integer $r_{k}$ such that $i \in L_{r_{k}}^{n_{k}}:=\left\{i_{1}\left(r_{k}\right), \ldots, i, \ldots, i_{\left|L_{r_{k}}\right|}^{n_{k}}\left(r_{k}\right)\right\}$. Then, from the definition of $y^{k, t}$ in (3.1) and (3.6) with $k$ and $t$ replaced, respectively, by $n_{k}$ and $r_{k}$, it is easy to verify that

$$
\begin{align*}
& 0 \leq \lim _{k \rightarrow \infty}\left\|T_{i} y^{n_{k}, r_{k}-1}-y^{n_{k}, r_{k}-1}\right\|^{2} \leq \lim _{k \rightarrow \infty}\left\|T_{i_{\max }\left(r_{k}\right)} y^{n_{k}, r_{k}-1}-y^{n_{k}, r_{k}-1}\right\|^{2}=0 \\
& \text { i.e., } \\
& \qquad \lim _{k \rightarrow \infty}\left\|T_{i} y^{n_{k}, r_{k}-1}-y^{n_{k}, r_{k}-1}\right\|=0 \tag{3.10}
\end{align*}
$$

By virtue of (3.9) with $t$ replaced by $r_{k},(3.10)$, the property of the sequence $\left\{x^{n_{k}}\right\}$ and the demiclosed property of $T_{i}, \tilde{p} \in \operatorname{Fix}\left(T_{i}\right)$ for any $i \in L$, i.e., $\tilde{p} \in C$. Similarly, any weak cluster point of $\left\{x^{k}\right\}$ belongs to $C$. Then, by Corollary 3.3.3 in [14], the sequence $\left\{x^{k}\right\}$ converges weakly to a point in $C$. This completes the proof.
$\square$ Next, in order to prove the strong convergence of any sequence, generated by our scheme with new $x^{k+1}$ in (3.2), we need the following Lemma.

Lemma 3.2 For any sequence, generated by our scheme with new $x^{k+1}$ in (3.2) and (c3) instead of (c2), is bounded. Moreover, we still have

$$
\begin{align*}
&\left\|x^{k+1}-p\right\|^{2} \leq\left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+2 \gamma_{k}\left(\left\langle F p, p-x^{k}\right\rangle+\gamma_{k}\|F p\| M_{1}\right) \\
&+2 \theta_{k}\left\|x^{k}-x^{k-1}\right\| M_{2}-\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \tag{3.11}
\end{align*}
$$

for all $k \geq k^{1}$, a positive integer, where $\gamma_{k}=t_{k} \mu_{k}$, $\beta_{k}=(1 / 2)\left(2 \eta-\gamma_{k} l^{2}\right), M_{1}$ and $M_{2}$ are some positive constants.

Proof. Put

$$
\eta_{k}=\frac{\left\langle F x^{k}-F x^{k-1}, x^{k}-x^{k-1}\right\rangle}{\left\|x^{k}-x^{k-1}\right\|^{2}} \quad \text { and } \quad l_{k}=\frac{\left\|F x^{k}-F x^{k-1}\right\|}{\left\|x^{k}-x^{k-1}\right\|} .
$$

It is easy to see that

$$
\eta \leq \eta_{k} \leq \frac{\left\|F x^{k}-F x^{k-1}\right\|}{\left\|x^{k}-x^{k-1}\right\|}=l_{k} \leq l
$$

and hence,

$$
\begin{equation*}
\frac{\eta}{l^{2}} \leq \mu_{k}=\frac{\eta_{k}}{l_{k}^{2}} \leq \frac{1}{\eta_{k}} \leq \frac{1}{\eta} \tag{3.12}
\end{equation*}
$$

Since $t_{k} \rightarrow 0$ as $k \rightarrow \infty$, from (3.12), we can confirm the existence of an integer $k^{1}$ such that $\gamma_{k} \in\left(0, \eta / l^{2}\right)$ and $\beta_{k} \geq \eta / 2$ for all $k \geq k^{1}$. Thus, by using Lemma $2.1,(3.3)$ and (3.12), we obtain

$$
\begin{aligned}
\left\|\left(I-\gamma_{k} F\right) x^{k}-p\right\| & =\left\|\left(I-\gamma_{k} F\right) x^{k}-\left(I-\gamma_{k} F\right) p-\gamma_{k} F p\right\| \\
& \leq\left(1-\gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|+\gamma_{k}\|F p\|
\end{aligned}
$$

and

$$
\begin{equation*}
\left\|y^{k, s}-p\right\| \leq\left\|u^{k}-p\right\| \leq\left\|x^{k}-p\right\|+t_{k} \frac{\theta_{k}}{t_{k}}\left\|x^{k}-x^{k-1}\right\| \tag{3.13}
\end{equation*}
$$

Let $c$ be a positive constant such that $\frac{\theta_{k}}{t_{k}}\left\|x^{k}-x^{k-1}\right\| \leq c$ for all $k \geq 0$. This constant exists due to (c3). Then,

$$
\begin{align*}
\left\|x^{k+1}-p\right\| & \leq\left(1-\alpha_{k}\right)\left\|\left(I-\gamma_{k} F\right) x^{k}-p\right\|+\alpha_{k}\left\|y^{k, s}-p\right\| \\
& \leq\left(1-\alpha_{k}\right)\left(\left(1-\gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|+\gamma_{k}\|F p\|\right)+\alpha_{k}\left(\left\|x^{k}-p\right\|+t_{k} c\right) \\
& \leq\left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|+2 \alpha_{k} \gamma_{k} \beta_{k}\left(\frac{\|F p\|}{\varepsilon \eta}+\frac{c l^{2}}{\eta^{2}}\right) \\
& \leq r:=\max \left\{\left\|x^{k^{1}}-p\right\|, 2\left(\|F p\| /(\varepsilon \eta)+c l^{2} / \eta^{2}\right)\right\} \forall k \geq k^{1} . \tag{3.14}
\end{align*}
$$

It means that $\left\{x^{k}\right\}$ is bounded. Consequently, $\left\|F x^{k}\right\| \leq M_{1}$ for all $k \geq 0$, where $M_{1}$ is some positive constant, that exists because $\left\{x^{k}\right\}$ is bounded and $F$ is $\tilde{l}$-Lipschitz continuous. Further, by Lemma 2.1,

$$
\begin{aligned}
\left\|\left(I-\gamma_{k} F\right) x^{k}-p\right\|^{2} & =\left\|\left(I-\gamma_{k} F\right) x^{k}-\left(I-\gamma_{k} F\right) p-\gamma_{k} F p\right\|^{2} \\
& \leq\left(1-\gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+2 \gamma_{k}\left(\left\langle F p, p-x^{k}\right\rangle+\gamma_{k}\|F p\| M_{1}\right)
\end{aligned}
$$

for all $k \geq k^{1}$. Clearly,

$$
\begin{aligned}
\left\|u^{k}-p\right\|^{2} & \leq\left\|x^{k}-p\right\|^{2}+2 \theta_{k}\left\langle x^{k-1}-x^{k}, u^{k}-p\right\rangle \\
& \leq\left\|x^{k}-p\right\|^{2}+2 \theta_{k}\left\|x^{k}-x^{k-1}\right\| M_{2}
\end{aligned}
$$

where, $M_{2}=r+t_{k} c \leq r+c$ for all $k \geq k^{1}$ due to (3.13), (3.14) and $t_{k} \in(0,1)$. Thus, (3.3) deduces

$$
\begin{equation*}
\left\|y^{k, s}-p\right\|^{2} \leq\left\|x^{k}-p\right\|^{2}+2 \theta_{k}\left\|x^{k}-x^{k-1}\right\| M_{2}-\rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \tag{3.15}
\end{equation*}
$$

Finally, by using Lemma 2.1 and (3.15) we have

$$
\begin{aligned}
\left\|x^{k+1}-p\right\|^{2} \leq & \left(1-\alpha_{k}\right)\left\|\left(I-\gamma_{k} F\right) x^{k}-p\right\|^{2}+\alpha_{k}\left\|y^{k, s}-p\right\|^{2} \\
\leq & \left(1-\alpha_{k}\right)\left[\left(1-\gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+2 \gamma_{k}\left(\left\langle F p, p-x^{k}\right\rangle+\gamma_{k}\|F p\| M_{1}\right)\right] \\
& +\alpha_{k}\left[\left\|x^{k}-p\right\|^{2}+2 \theta_{k}\left\|x^{k}-x^{k-1}\right\| M_{2}\right. \\
& \left.\quad-\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}\right] \\
\leq & \left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+2 \gamma_{k}\left(\left\langle F p, p-x^{k}\right\rangle+\gamma_{k} M_{1}\right) \\
& +2 \theta_{k}\left\|x^{k}-x^{k-1}\right\| M_{2}-\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}
\end{aligned}
$$

that is (3.11). The proof is completed. $\square$ Now, we are in the position to prove a strong convergence result.
Theorem 3.3 Any sequence, generated by our block-iterative scheme with new $x^{k+1}$ and (c3) instead of (c2), as $k \rightarrow \infty$, converges strongly to a point $p_{*} \in H$, solving (1.1).

Proof. Obviously, from (3.12) and the definitions of $\gamma_{k}, \beta_{k}$ in Lemma 3.2, we get

$$
\begin{equation*}
\theta_{k}\left\|x^{k}-x^{k-1}\right\|=t_{k} \frac{\theta_{k}}{t_{k}}\left\|x^{k}-x^{k-1}\right\| \leq \gamma_{k} \beta_{k}\left(2 l^{2} / \eta^{2}\right) \tau_{k} \tag{3.16}
\end{equation*}
$$

where, following condition (c3), $\tau_{k}=\left(\theta_{k} / t_{k}\right)\left\|x^{k}-x^{k-1}\right\| \rightarrow 0$ as $k \rightarrow \infty$. Then, from (3.11), $\beta_{k} \geq \eta / 2, \alpha_{k} \in[\varepsilon, 1]$ and the last inequality, we have

$$
\begin{align*}
\left\|x^{k+1}-p\right\|^{2} \leq & \left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+4 \gamma_{k} \beta_{k}\left[\left\langle F p, p-x^{k}\right\rangle+\gamma_{k}\|F p\| M_{1}\right] / \eta \\
& +2 \gamma_{k} \beta_{k}\left(2 l^{2} / \eta^{2}\right) \tau_{k} M_{2}-\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \\
\leq & \left(1-\varepsilon \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+\varepsilon \gamma_{k} \beta_{k} 4\left[\left(\left\langle F p, p-x^{k}\right\rangle+\gamma_{k}\|F p\| M_{1}\right) / \eta\right. \\
& \left.+\left(l^{2} / \eta^{2}\right) \tau_{k} M_{2}\right] / \varepsilon-\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \tag{3.17}
\end{align*}
$$

Now, we need only to consider two cases.
Case 1. $\left\|x^{k+1}-p\right\| \leq\left\|x^{k}-p\right\|$ for all $k \geq k^{1}$.
Then there exists $\lim _{k \rightarrow \infty}\left\|x^{k}-p\right\|$ and it is easy to see from (3.17) that

$$
\begin{equation*}
\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \leq\left\|x^{k}-p\right\|^{2}-\left\|x^{k+1}-p\right\|^{2}+d_{k} \gamma_{k} \tag{3.18}
\end{equation*}
$$

where $d_{k}=4 \beta_{k}\|F p\|\left[\left(r+\gamma_{k} M_{1}\right) / \eta\right)+\tau_{k} M_{2} l^{2} / \eta^{2}$. Next, we prove that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}=0 \tag{3.19}
\end{equation*}
$$

Clearly, if

$$
\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \leq d_{k} \gamma_{k}
$$

for all $k \geq k^{1}$, then (3.19) holds. If

$$
0 \leq \varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}>d_{k} \gamma_{k}
$$

for all $k \geq k^{1}$, then from (3.18) it follows that

$$
\sum_{k=k^{1}}^{M}\left(\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}-d_{k} \gamma_{k}\right) \leq\left\|x^{k^{1}}-p\right\|^{2}-\left\|x^{M+1}-p\right\|^{2}
$$

for any positive integer $M$. Thus,

$$
\sum_{k=k^{1}}^{\infty}\left(\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}-d_{k} \gamma_{k}\right) \leq\left\|x^{k^{1}}-p\right\|^{2}
$$

Therefore,

$$
\lim _{k \rightarrow \infty}\left(\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}-d_{k} \gamma_{k}\right)=0
$$

and hence, we obtain (3.19), because $\gamma_{k} \rightarrow 0$. By the similar argument as in the proof of Theorem 3.1, we get (3.6)-(3.10) and that any weak cluster point of $\left\{x^{k}\right\}$ belongs to $C$. Therefore,

$$
\begin{equation*}
\limsup _{k \rightarrow \infty}\left\langle F p_{*}, p_{*}-x^{k}\right\rangle \leq 0 \tag{3.20}
\end{equation*}
$$

Now, from (3.17), we obtain

$$
\begin{equation*}
\left\|x^{k+1}-p_{*}\right\|^{2} \leq\left(1-b_{k}\right)\left\|x^{k}-p_{*}\right\|^{2}+b_{k} c_{k} \tag{3.21}
\end{equation*}
$$

where $b_{k}=\varepsilon \gamma_{k} \beta_{k}$ and

$$
c_{k}=4\left[\left(\left\langle F p, p-x^{k}\right\rangle+\gamma_{k}\|F p\| M_{1}\right) / \eta+\left(l^{2} / \eta^{2}\right) \tau_{k} M_{2}\right] / \varepsilon
$$

Clearly, $\sum_{k=1}^{\infty} b_{k} \geq \sum_{k=1}^{\infty} \varepsilon t_{k} \eta^{2} /\left(2 l^{2}\right)=\infty$ and from (3.20) with $\gamma_{k}, \tau_{k} \rightarrow 0$ it follows that $\lim \sup _{k \rightarrow \infty} c_{k} \leq 0$. So, applying Lemma 2.3 to (3.21) with $a_{k}=\left\|x^{k}-p_{*}\right\|^{2}$, we get $\lim _{k \rightarrow \infty}\left\|x^{k}-p_{*}\right\|=0$.
Case 2. There exists a subsequence $\left\{l_{k}\right\} \subset\{k\}$ such that $\left\|x^{l_{k}}-p\right\| \leq\left\|x^{l_{k}+1}-p\right\|$ for all $k \geq k^{1}$.

Then, by Lemma 2.3, there exists a non-decreasing sequence $\left\{m_{k}\right\} \subseteq\{k\}$ such that $m_{k} \rightarrow \infty$,

$$
\begin{equation*}
\left\|x^{m_{k}}-p\right\| \leq\left\|x^{m_{k}+1}-p\right\| \quad \text { and } \quad\left\|x^{k}-p\right\| \leq\left\|x^{m_{k}+1}-p\right\| \tag{3.22}
\end{equation*}
$$

for each $k \geq k^{1}$. Hence, from (3.16), (3.17) and the first inequality in (3.22), we have

$$
\begin{equation*}
\left\|x^{m_{k}}-p\right\|^{2} \leq 4\left[\left(\left\langle F p, p-x^{k}\right\rangle+\gamma_{k}\|F p\| M_{1}\right) / \eta+\left(l^{2} / \eta^{2}\right) \tau_{k} M_{2}\right] / \varepsilon \tag{3.23}
\end{equation*}
$$

and

$$
\varepsilon \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{m_{k}, t-1}-y^{m_{k}, t-1}\right\|^{2} \leq d_{m_{k}} \gamma_{m_{k}}
$$

Hence,

$$
\lim _{k \rightarrow \infty}\left\|T_{i_{\max }(t)} y^{m_{k}, t-1}-y^{m_{k}, t-1}\right\|^{2}=0
$$

for each $t=1, \cdots, s$. By the similar argument as in the proof of Theorem 3.1,

$$
\lim _{k \rightarrow \infty}\left\|T_{i} y^{m_{k}, r_{k}-1}-y^{m_{k}, r_{k}-1}\right\|=0 \quad \text { and } \quad \lim _{k \rightarrow \infty}\left\|x^{m_{k}}-y^{m_{k}, r_{k}-1}\right\|=0
$$

So, any weak cluster point of $\left\{x^{m_{k}}\right\}$ belongs to $C$. Consequently,

$$
\limsup _{k \rightarrow \infty}\left\langle F p_{*}, p_{*}-x^{m_{k}}\right\rangle \leq 0
$$

Using (3.23) with $p$ changed by $p_{*}$, the above limsup and $\gamma_{m_{k}}, \tau_{m_{k}} \rightarrow 0$, we obtain

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|x^{m_{k}}-p_{*}\right\|=0 \tag{3.24}
\end{equation*}
$$

Again, from (3.17) with $k$ and $p$ replaced, respectively, by $m_{k}$ and $p_{*}$, we get $\left\|x^{m_{k}+1}-p_{*}\right\|^{2} \leq\left\|x^{m_{k}}-p_{*}\right\|^{2}+4 \gamma_{m_{k}} \beta_{m_{k}}\left[\|F p\|\left(r+\gamma_{m_{k}} M_{1}\right) / \eta+\left(l^{2} / \eta^{2}\right) \tau_{m_{k}} M_{2}\right]$.

From the last inequality, (3.24), $\gamma_{m_{k}}, \tau_{m_{k}} \rightarrow 0$ and $\beta_{k} \leq \eta$ for all $k \geq k^{1}$, it follows that $\lim _{m \rightarrow \infty}\left\|x^{m_{k}+1}-p_{*}\right\|^{2}=0$. The last limit together with the second inequality in (3.22) implies that $\lim _{k \rightarrow \infty}\left\|x^{k}-p_{*}\right\|=0$. This completes the proof.

## Remarks

2. If the given $T_{i}$ is quasi-nonexpansive, then the relaxation $\bar{T}_{i}=I+\beta(T-I)$ satisfies the condition

$$
\left\|\bar{T}_{i} x-p\right\|^{2} \leq\|x-p\|^{2}-\lambda\left\|T_{i} x-x\right\|^{2} \forall x \in H, p \in \operatorname{Fix}\left(T_{i}\right)
$$

for any fixed $\beta \in(0,1]$ where $\lambda=\beta(1-\beta)$. It is easy to see that $\bar{T}_{i}$ is demiclosed if and only if $T$ does. Moreover, we still have that $\operatorname{Fix}\left(T_{i}\right)=\operatorname{Fix}\left(\bar{T}_{i}\right)$ (see, [21]). Analyzing the proofs of the Theorems, we obtain that they are also valid, when we replace $T_{i(t)}$ in (3.1) by $\bar{T}_{i(t)}$.
3. Take $F=I-u$ for some fixed point $u \in H$. Clearly, $F$ is $\eta$-strongly monotone with any $\eta \in(0,1]$ and $\gamma$-Lipschitz continuous with any $\gamma \geq 1$. Clearly, in this case, $\mu_{k}=1$ for all $k \geq 1$. Then, $x^{k+1}$ in the methods listed above has the form,

$$
\begin{equation*}
x^{k+1}=\left(1-\alpha_{k}\right)\left(1-t_{k}\right) x^{k}+\left(1-\alpha_{k}\right) t_{k} u+\alpha_{k} y^{k, s} \tag{3.25}
\end{equation*}
$$

Taking $u=0$ in (3.25), we obtain an improvement modification for the selective inertial block-iterative scheme,

$$
\begin{equation*}
x^{k+1}=\left(1-\alpha_{k}\right)\left(1-t_{k}\right) x^{k}+\alpha_{k} y^{k, s} \tag{3.26}
\end{equation*}
$$

for all $k \geq 0$. Note that any sequence, generated by (3.26) converges strongly to a minimal-norm point of $C$, as $k \rightarrow \infty$.
4. Now, we consider the case when the expression $x^{k+1}$ in (3.2) is replaced by

$$
\begin{equation*}
x^{k+1}=\left(1-\alpha_{k}\right) y^{k, s}+\alpha_{k}\left(I-t_{k} \mu_{k} F\right) y^{k, s} \tag{3.27}
\end{equation*}
$$

with a new

$$
\mu_{k}=\left\{\begin{array}{lc}
\frac{\left\langle F y^{k, s}-F y^{k-1, s}, y^{k, s}-y^{k-1, s}\right\rangle}{\left\|F y^{k, s}-F y^{k-1, s}\right\|^{2}}, & y^{k, s} \neq y^{k-1, s}  \tag{3.28}\\
\mu_{k-1}, & \text { otherwise }
\end{array}\right.
$$

$y^{-1, s}=x^{-1}$ and $y^{0, s}=x^{0}$. Then, the inequalities in (3.12) are still true. Moreover, $\gamma_{k} \in\left(0, \eta / l^{2}\right)$ and $\beta_{k} \geq \eta / 2$ for all $k \geq k^{2}$, some positive constant. Next, from (3.13) and $\frac{\theta_{k}}{t_{k}}\left\|x^{k}-x^{k-1}\right\| \leq c$, we get

$$
\left\|y^{k, s}-p\right\| \leq\left\|x^{k}-p\right\|+t_{k} c \forall k \geq 0
$$

Consequently,

$$
\begin{aligned}
\left\|x^{k+1}-p\right\| & \leq\left(1-\alpha_{k}\right)\left\|y^{k, s}-p\right\|+\alpha_{k}\left\|\left(I-\gamma_{k} F\right) y^{k, s}-p\right\| \\
& \leq\left(1-\alpha_{k}\right)\left(\left\|x^{k}-p\right\|+t_{k} c\right)+\alpha_{k}\left[\left(1-\gamma_{k} \beta_{k}\right)\left(\left\|x^{k}-p\right\|+t_{k} c\right)+\gamma_{k}\|F p\|\right] \\
& \leq\left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|+t_{k} c+\alpha_{k} \gamma_{k}\|F p\| \\
& \leq\left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|+\alpha_{k} \gamma_{k} \beta_{k}\left(c /\left(\alpha_{k} \mu_{k} \beta_{k}\right)+\|F p\| / \beta_{k}\right) \\
& \leq r^{\prime}=\max \left\{\left\|x^{k_{1}}-p\right\|, 2\left(c l^{2} /\left(\varepsilon \eta^{2}\right)+\|F p\| / \eta\right)\right\}
\end{aligned}
$$

a positive constant, for all $k \geq k^{2}$. It means that $\left\{x^{k}\right\}$ is bounded. Hence, $\left\{y^{k, s}\right\}$ is also bounded. Then, $\left\|F y^{k, s}\right\| \leq M_{1}^{\prime}$, some positive constants, and

$$
\begin{aligned}
\left\|x^{k+1}-p\right\|^{2} \leq & \left(1-\alpha_{k}\right)\left\|y^{k, s}-p\right\|^{2}+\alpha_{k}\left\|\left(I-\gamma_{k} F\right) y^{k, s}-p\right\|^{2} \\
\leq & \left(1-\alpha_{k}\right)\left\|y^{k, s}-p\right\|^{2}+\alpha_{k}\left[\left(1-\gamma_{k} \beta_{k}\right)\left\|y^{k, s}-p\right\|^{2}\right. \\
& \left.\quad+2 \gamma_{k}\left(\left\langle F p, p-y^{k, s}\right\rangle+\gamma_{k}\left\langle F p, F y^{k, s}\right\rangle\right)\right] \\
\leq & \left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|y^{k, s}-p\right\|^{2}+2 \gamma_{k}\left(\left\langle F p, p-y^{k, s}\right\rangle+\gamma_{k}\|F p\| M_{1}^{\prime}\right) .
\end{aligned}
$$

This together with (3.15) and (3.16) implies that

$$
\begin{aligned}
\left\|x^{k+1}-p\right\|^{2} \leq & \left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+\alpha_{k} \gamma_{k} \beta_{k}\left(2 l^{2} /\left(\varepsilon \eta^{2}\right)\right) \tau_{k} \\
& \quad-\left(1-\alpha_{k} \gamma_{k} \beta_{k}\right) \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} \\
& +4 \alpha_{k} \gamma_{k} \beta_{k}\left(\left\langle F p, p-y^{k, s}\right\rangle+\gamma_{k}\|F p\| M_{1}^{\prime}\right) /(\varepsilon \eta) \\
\leq & \left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+2 \alpha_{k} \gamma_{k} \beta_{k}\left[\left(l^{2} / \eta\right) \tau_{k}+2\left\langle F p, p-x^{k}\right\rangle\right. \\
& \left.+\|F p\|\left(2\left\|y^{k, s}-x^{k}\right\|+\gamma_{k} M_{1}^{\prime}\right)\right] /(\varepsilon \eta) \\
& -\left(1-\alpha_{k} \gamma_{k} \beta_{k}\right) \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2} .
\end{aligned}
$$

Since $\gamma_{k} \rightarrow 0, \alpha_{k}>\varepsilon$ and $\beta_{k} \geq \eta / 2$ for all $k \geq k^{1}$, there exists a positive integer $\tilde{k} \geq k^{1}$ such that, for all $k \geq \tilde{k}, 1-\alpha_{k} \gamma_{k} \beta_{k} \geq \tilde{c}$, a positive constant.

Therefore, the last inequality yields

$$
\begin{aligned}
\left\|x^{k+1}-p\right\|^{2} \leq & \left(1-\alpha_{k} \gamma_{k} \beta_{k}\right)\left\|x^{k}-p\right\|^{2}+2 \alpha_{k} \gamma_{k} \beta_{k}\left[\left(l^{2} / \eta\right) \tau_{k}+2\left\langle F p, p-x^{k}\right\rangle\right. \\
& \left.+\|F p\|\left(2\left\|y^{k, s}-x^{k}\right\|+\gamma_{k} M_{1}^{\prime}\right)\right] /(\varepsilon \eta) \\
& -\tilde{c} \rho_{\min } \sum_{t=1}^{s}\left\|T_{i_{\max }(t)} y^{k, t-1}-y^{k, t-1}\right\|^{2}
\end{aligned}
$$

where $\lim _{k \rightarrow \infty}\left\|y^{k, s}-x^{k}\right\|=0$ due to (3.8). Repeating step by step the proof of Theorem 3.3, we obtain the following result.
Theorem 3.4 Any sequence $\left\{x^{k}\right\}$, generated by the main scheme with new $x^{k+1}$, defined by (3.27) and (3.28), as $k \rightarrow \infty$, converges strongly to the point $p_{*}$, solving (1.1).
4. Taking $\alpha_{k}=1$ for all $k \geq 0$, (3.27) has the form,

$$
\begin{equation*}
x^{k+1}=\left(I-t_{k} \mu_{k} F\right) y^{k, s} \tag{3.29}
\end{equation*}
$$

that together with $\theta_{k}=0$ is the steepest descent block iterative method, studied in [7] with $\mu_{k}=\mu \in\left(0,2 \eta / l^{2}\right)$ and $y^{k, s}=x^{k, s}$. In the case that $F=I-u$, we have the following Halpern's selective inertial block-iterative scheme, that is the our main inertial iterative scheme with $x^{k+1}$ in (3.29) replaced by

$$
\begin{equation*}
x^{k+1}=t_{k} u+\left(1-t_{k}\right) y^{k, s} \tag{3.30}
\end{equation*}
$$

since, in this case, $\mu_{k}=1$ for all $k \geq 0$.

## 4. Applications and computational experiments

We consider a networked system consisting of an operator, who manages the system, and a finite number $m-1$ of participating users. In the system the manage operator can be seen as an user $m$. We suppose that each $i$-user has its own private objective function $f_{i}$ on $\mathbb{E}^{n}$, an $n$-dimensional Euclidian space, and own capacity constraint, depicted by a nonempty closed convex $C_{i}$ in $\mathbb{E}^{n}$. Moreover, the following is assumed.

- $T_{i}$ is a mapping on $\mathbb{E}^{n}$ with $\operatorname{Fix}\left(T_{i}\right)=C_{i}$ for each $i \in L$ and $\cap_{i \in L} \operatorname{Fix}\left(T_{i}\right) \neq$ $\emptyset$.
- $f_{i}$ is a concave and Fréchet differentiable function on $\mathbb{E}^{n}$ such that $-\nabla f_{i}$ is $\eta_{i}$-strongly monotone and $l_{i}$-Lipschitz continuous.
- User $i \in L$ can use its own private $C_{i}$ and $f_{i}$.
- The operator can communicate with all users.

The considered problem is formulated as finding a point $p_{*}$ in $\mathbb{E}^{n}$ such that

$$
\begin{equation*}
f\left(p_{*}\right)=\max _{p \in C} f(p), f(x)=\sum_{i \in L} f_{i}(x), C=\cap_{i \in L} \operatorname{Fix}\left(T_{i}\right) \tag{4.1}
\end{equation*}
$$

Problem (4.1) is closely related to network recourse allocation [5,28] which is a central issue in modern communication networks. The main objective of the problem is to share the available resources among users in the network so as to maximize the sum of their utilities subject to the feasible regions for allocating the resources. This problem is equivalent to the following one, $\tilde{f}\left(p_{*}\right)=\inf _{p \in C} \tilde{f}(p)$, where $\tilde{f}=-\sum_{i \in L} f_{i}(x)$ is convex and Fréchet differentiable with $\eta$-strongly monotone and $l$-Lipschitz continuous $\nabla \tilde{f}$ where $\tilde{l}=\max _{i \in L} l_{i}$ and $\eta=\min _{i \in L} \eta_{i}$. To solve (4.1), when $-\nabla f_{i}$ is $\eta_{i}$-strongly monotone and $l_{i}$-Lipschitzian and $T_{i}$ is quasi-nonexpansive, Iiduka [18] introduced a parallel optimization algorithm, at each iteration steep of which the value $\mu$ is chosen in dependence of $\eta_{i}$ and $l_{i}$. It is easy to see that the considered problem can be solved by any method, generated by one of our schemes, where $F=\nabla \tilde{f}$ and $C$ is given in (4.1).

For computations, we consider the case, when $\tilde{f}$ is a differentiable convex function, the derivative of which, $F x:=\tilde{f}^{\prime}(x)$, is $\eta$-strongly monotone and $\tilde{l}$-Lipschitz continuous and $T_{i}$ is the subgradient projection relative to a convex function $g_{i}$, defined by

$$
P_{g_{i}} x:= \begin{cases}x-\frac{\left[g_{i}(x)\right]_{+}}{\left\|\eta_{i}(x)\right\|^{2}} \eta_{i}(x), & \text { if } \eta_{i}(x) \neq 0 \\ x, & \text { otherwise }\end{cases}
$$

where $\eta_{i}(x) \in \partial g_{i}(x):=\left\{z \in \mathbb{E}^{n}: g_{i}(y)-g_{i}(x) \geq\langle z, y-x\rangle\right.$, for all $\left.y \in \mathbb{E}^{n}\right\}$, called a subgradient of $g_{i}$. We know in [14] that $T_{i}:=P_{g_{i}}$ is a demiclosed cutter and $\operatorname{Fix}\left(T_{i}\right)=\left\{z \in \mathbb{E}^{n}: g_{i}(z) \leq 0\right\}$. We take a function $\tilde{f}(x)=\|x-u\|^{2} / 2$ and $g_{i}(x)=\left\|x-P_{Q_{i}} x\right\|^{2} / 2$ for $i \in L$, where $P_{Q_{i}}$ is the metric projection of $\mathbb{E}^{n}$ onto the set $Q_{i}=\left\{x \in \mathbb{E}^{n}:\left\|x-a^{i}\right\|^{2} \leq 1\right\}$ and $a^{i}$ are points in $\mathbb{E}^{n}$ such that $\cap_{i \in L} Q_{i} \neq \emptyset$. Clearly, $\partial g_{i}(x)=g_{i}^{\prime}(x)=x-P_{Q_{i}} x$ and

$$
P_{Q_{i}} x= \begin{cases}a^{i}+\frac{1}{\left\|x-a^{i}\right\|}\left(x-a^{i}\right), & \text { if }\left\|x-a^{i}\right\|>1 \\ x, & \text { otherwise }\end{cases}
$$

Therefore,

$$
P_{g_{i}} x:= \begin{cases}\left(x+P_{Q_{i}} x\right) / 2, & \text { if } \eta_{i}(x) \neq 0 \\ x, & \text { otherwise }\end{cases}
$$

The numerical results, calculated with $n=5, m=6$,

$$
\begin{aligned}
& a^{1}=(0 ;-1 / 2 ; 0 ; 0 ; 0), a^{2}=(0 ; 1 / 2 ; 0 ; 0 ; 0), a^{3}=(1 / 2 ; 0 ; 0 ; 0 ; 0) \\
& a^{4}=(-1 / 2 ; 0 ; 0 ; 0 ; 0), a^{5}=(0 ; 0 ; 1 / 2 ; 0 ; 0), a^{6}=(0 ; 0 ;-1 / 2 ; 0 ; 0)
\end{aligned}
$$

$L=L_{1}^{k} \cup L_{2}^{k}$, where $L_{1}^{k}=\{1,2,3\}$ and $L_{2}^{k}=\{4,5,6\}$. Taking $u=(0 ; 0 ; 0 ; 0 ; 0)$, we get the unique solution $p_{*}=(0 ; 0 ; 0 ; 0 ; 0)$. Numerical results, obtained without the inertial term $\left(\theta_{k}=0\right)$, are calculated by the formula

$$
\begin{align*}
x^{k, 1} & =T_{i_{\max }(1)} x^{k, 0}, i_{\max }(1)=\arg \max _{i \in L_{1}^{k}}\left\|T_{i} x^{k, 0}-x^{k, 0}\right\| \\
x^{k, 2} & =T_{i_{\max }(2)} x^{k, 1}, i_{\max }(2)=\arg \max _{i \in L_{2}^{k}}\left\|T_{i} x^{k, 1}-x^{k, 1}\right\|  \tag{4.2}\\
x^{k+1} & =\left(1-t_{k}\right) x^{k, 2}
\end{align*}
$$

following from (3.30), with the started point $x^{0}=(2 ; 2.5 ; 3 ; 3.5 ; 1)$.

Table 1. Numerical results by method (4.2)
The following numerical table is obtained by using our iterative scheme

$$
\begin{align*}
u^{k} & =x^{k}+\theta_{k}\left(x^{k}-x^{k-1}\right), y^{k, 0}=u^{k} \\
y^{k, 1} & =T_{i_{\max }(1)} y^{k, 0}, i_{\max }(1)=\arg \max _{i \in L_{1}^{k}}\left\|T_{i} y^{k, 0}-y^{k, 0}\right\| \\
y^{k, 2} & =T_{i_{\max }(2)} y^{k, 1}, i_{\max }(2)=\arg \max _{i \in L_{2}^{k}}\left\|T_{i} y^{k, 1}-y^{k, 1}\right\|  \tag{4.3}\\
x^{k+1} & =\left(1-t_{k}\right) y^{k, 2}
\end{align*}
$$

with

$$
\theta_{k}= \begin{cases}\min \left\{\varepsilon_{k} /\left\|x^{k}-x^{k-1}\right\|, \theta\right\}, & \text { if } x^{k} \neq x^{k-1} \leq 0  \tag{4.4}\\ \theta_{k-1}, & \text { otherwise }\end{cases}
$$

where $\varepsilon_{k}=1 /(k+1)^{2}, \theta=0.1$ and $x^{-1}=(1 ; 3.5 ; 3 ; 2.5 ; 2)$, and the same values for other parameters. We get the numerical results in Table 2.

Table 2. Numerical results by method (4.3) and (4.4)
The numerical results in Tables 1 and 2 show the effectiveness of the introduced schemes. Moreover, they also show that the results calculated by using the inertial term $u^{k}$ is better than that without the same term.

## 5. Conclusion

In this paper, for finding a point in the set common fixed points of a finite family of demiclosed strongly quasi-nonexpansive mappings in Hilbert spaces, we suggested a selective inertial block-iterative schemes with weak convergence. Then, based on a specific combination of the scheme with the steepest-descent method, we propose new schemes, for solving a variational inequality problem over the set of common fixed points of a finite family of SQNE mappings in Hilbert spaces. The strong convergence of the latter scheme is proved without the approximately shrinking and boundedly regular assumptions on the mappings and their fixed point sets, respectively, that are usually required recently in literature. An application to a networked system and computational experiments are given for illustration and comparison.
